Description

TECHNICAL FIELD OF THE INVENTION

- 5 [0001] The present invention relates to the preparation of triethylenediamine (TEDA) by contacting nitrogen-containing compounds with zeolites at elevated temperature.

BACKGROUND OF THE INVENTION

- 10 [0002] The synthesis of TEDA from a variety of amine compounds using metallosilicates is well known in the art.
[0003] U.S. 3,956,329 discloses a process for preparing TEDA from a number of amine compounds using untreated zeolite catalysts with a $\text{SiO}_2/\text{Al}_2\text{O}_3$ (silica to alumina) ratio between 2 and 12.
[0004] U.S. 4,804,758 discloses the preparation of TEDA from certain heterocyclic amines in the presence of borosilicate and/or iron silicate zeolites as catalysts.
15 [0005] U.S. 4,966,989 and 5,041,548 disclose the preparation of TEDA from amine compounds using a catalyst comprising a crystalline metallosilicate having a silica/metal oxide molar ratio of 12/1 or more, in particular, a metallosilicate crystallized in the presence of an organic crystallizing agent.
[0006] EP 158 319 discloses a method of preparing TEDA by contacting acyclic or heterocyclic amines with untreated high-silica zeolite having a silica to alumina ratio of at least 20 to 1.
20 [0007] EP 382 055 discloses a process for synthesizing TEDA from ethylenediamine and 0 to 200 mole% piperazine on aluminum, boron, gallium and/or iron silicate zeolites.
[0008] EP 423 526 discloses the preparation of TEDA and piperazine from ethylenediamine-water mixtures which is catalyzed by zeolites of the pentasil type with weakened acidity, i.e., which contain alkali metal ions or in which the aluminum of the zeolite skeleton has been isomorphously replaced by iron.
25 [0009] EP 312 734 discloses that piperazine can be converted directly to TEDA in the presence of zeolites, preferably untreated zeolites having a pentasil, especially a ZSM-5, structure.
[0010] EP 313 753 discloses the preparation of mixtures of TEDA and piperazine from polyethylene polyamines and/or ethanolamines using an untreated pentasil zeolite.
[0011] The following references disclose caustic treatment of zeolites:
30 [0012] U.S. 4,730,025 discloses a method for purifying zeolitic materials comprising a plurality of solid crystalline phases which uses the variation in solubility between the phase components comprising the materials. Impure zeolite is contacted with a caustic solution under conditions which dissolve at least one of the phases, and the resulting zeolitic material is filtered and washed to produce a purified product. Col 3/23+ states that it is known in the art to expose a zeolite to conditions of high alkalinity to effect a change.
35 [0013] Liu, et al. (*J. Chem. Soc., Chem. Commun.*, 1988, p582) reports the treatment of ultra-stable zeolite Y with an aqueous solution of KOH where non-framework Al was reinserted to the zeolite lattice upon treatment.
[0014] Desau, et al. (*Zeolites*, 1992, vol. 12, p776) shows that treatment of ZSM-5 crystals with an aqueous base solution resulted in partial dissolution of the sample with preferential removal of silica.

40 SUMMARY OF THE INVENTION

- [0015] The present invention is directed to a process for preparing TEDA by contacting an amine-containing compound with a pentasil-type zeolite in the hydrogen (H^+) and/or ammonium (NH_4^+) form at elevated temperatures. The zeolite catalyst used in the process is one which has been treated with an aqueous caustic solution prior to its conversion to the H^+ or NH_4^+ form.
45 [0016] Such caustic treatment at least partially deactivates the external sites of the zeolite catalyst for acid catalyzed reactions and surprisingly improves the selectivity toward TEDA production. Some of the amine compounds typically used in making TEDA, such as ethylenediamine (EDA), are very reactive on the external sites of zeolite catalysts giving undesired products.

50 DETAILED DESCRIPTION OF THE INVENTION

- [0017] As the starting material to be used in the process for preparing TEDA, any amine compounds having, in the molecule, a moiety represented by the following general formula can be used:
55

EP 0 831 096 B1

where X is oxygen or nitrogen. Typical examples of suitable amine compounds are ethanolamines, including monoethanolamine, diethanolamine and triethanolamine; ethylenamines, including ethylenediamine, diethylenetriamine and triethylenetetramine; piperazine and its derivatives N-hydroxyethylpiperazine and N-aminoethylpiperazine; morpholine and obviously mixtures of the foregoing.

5 [0018] The crystalline metallosilicate (zeolite), which is used as the catalyst in the process, has a crystal skeleton mainly comprised of silicon dioxide (silica; SiO_2) and aluminum oxide (alumina; Al_2O_3), iron oxide or boron oxide. Alumina is the preferred metal oxide. The silica/metal oxide molar ratio is 12:1 or more, preferably 25:1 to 1000:1, and more preferably 50:1 to 500:1. If the silica/metal oxide molar ratio is less than 12:1, the yield of TEDA is undesirably low.

10 [0019] There are no special limitations to the crystalline aluminosilicate that is used as long as it satisfies the above silica/alumina molar ratio, has a main pore made of a ten-membered ring of oxygen and belongs to members of the pentasil-type structure, ZSM-5 zeolite being most preferred.

[0020] The preparation of suitable pentasil zeolite catalysts is well known to those skilled in the art as illustrated by the previously cited patents and literature references. In addition, suitable pentasil zeolites are commercially available from many sources such as Degussa AG and CU Chemie Uetikon AG.

15 [0021] Crystalline aluminosilicates of the pentasil family as obtained by the hydrothermal synthesis using an organic crystallizing agent are particularly preferred. Among the pentasil types, the zeolite structures ZSM-5, ZSM-11, ZSM-8, and ZSM-5/ZSM-11-intermediates are preferred, especially ZSM-5.

[0022] The zeolite catalysts are used in their hydrogen form (H^+) and/or their ammonium form (NH_4^+) after having undergone the aqueous caustic solution pretreatment.

20 [0023] For example, a pentasil-type crystalline aluminosilicate can be prepared by the hydrothermal synthesis using a mixture composed mainly of a silica source, e.g., colloidal silica, silica gel, or silicic acid salts such as water glass, and an aluminum oxide source, e.g., the sulfuric acid salts, nitric acid salts or oxy acid salts of alumina, such as aluminum sulfate and sodium aluminate, in the absence or preferably in the presence of an organic crystallizing agent, e.g., amines such as tetraalkylammonium halide having 2 to 5 carbon atoms.

25 [0024] There is also known a method in which the hydrothermal synthesis is performed in the presence of alkali metal compounds such as the hydroxides and halides of alkali metal such as sodium. The crystalline aluminosilicate obtained by these methods is generally not of the H^+ or NH_4^+ form, but of the form that H^+ and NH_4^+ are replaced by quaternary ammonium ion and/or alkali metal ion such as Na^+ . Therefore, the crystalline aluminosilicate must be changed into the H^+ or NH_4^+ form, and this exchange can be easily achieved by known methods after the aqueous caustic solution treatment.

30 [0025] With regard to the caustic treatment, the prepared aluminosilicate is contacted, for example, with an aqueous 0.1 to 5 molar caustic solution, such as sodium or potassium hydroxide or even ammonium hydroxide, at 0 to 100°C for 0.01 to 100 hours, preferably 0.5 to 3 molar caustic solution at 20 to 80°C for 0.5 to 5 hours. It is desirable to perform such contact using 10 to 30 mL aqueous solution/g zeolite.

35 [0026] For changing the alkali metal ion of the caustic treated zeolite into H^+ or NH_4^+ , there is often employed a method in which the alkali metal salt-type crystalline aluminosilicate is treated with an aqueous solution of ammonium salts, such as ammonium nitrate and ammonium sulfate, to form an ammonium salt-type crystalline aluminosilicate. The ammonium salt-type crystalline aluminosilicate may then be calcined in the air at a temperature of 300 to 600°C , preferably 400 to 500°C , to obtain the H^+ form crystalline zeolite.

40 [0027] The caustic treated and then exchanged zeolite as used in the present invention is of the H^+ and/or NH_4^+ form. The H^+ and/or NH_4^+ may be partially replaced by other cations, such as alkali, alkaline earth, rare earth, transition metals, oxides, as long as the object of the present invention can be obtained.

[0028] The catalyst of the present invention can be used in any desired form, such as powder, particles, strips, spheres and pellets. The catalyst can be self-bound or molded with a binder such as silica, alumina, titania, zirconia, natural clays and/or mixtures of these materials be mixed with the zeolite. Naturally occurring clays which can be composited with the zeolite catalyst include the montmorillonite and kaolin family. These clays can be used in the raw state as originally mined or initially subjected to calcination, acid treatment or chemical modification.

45 [0029] Of all the matrix materials mentioned above, materials of low acidity such as silica or zirconia are preferred in that they prevent unwanted side reactions engendered by more active materials such as alumina. The performance of alumina can, however, be improved by altering its acid properties via chemical modification.

50 [0030] The relative proportions of zeolite and matrix material can vary widely with the zeolite content ranging from 10 to 98 wt%, and more usually in the range of 50 to 90 wt%, of the composite.

[0031] In accordance with the process of the present invention, the desired TEDA can be efficiently obtained by reacting amine compounds having in the molecule a group represented by the general formula:

55

EP 0 831 098 B1

as the starting material using the described zeolite catalyst under pressures ranging from 0.001 to 200 atm (0.1 to 20,000 kPa), preferably 0.01 to 10 atm (1 to 1000 kPa).

[0032] The reaction of the amine compound proceeds on contacting it with the described zeolite catalyst under the above-specified pressure. Reaction conditions, such as reaction temperature, reaction time and starting materials/catalyst ratio, cannot be determined unconditionally because they vary with the type of amine compound, the type of zeolite catalyst, reaction pressure. Usually the reaction temperature is chosen within the range 100 to 450°C, preferably 300 to 400°C.

[0033] The reaction can be performed batch-wise, semi-continuously or continuously. In the case of the continuous reaction, WHSV (weight hourly space velocity) is not critical, but usually ranges from 0.01 to 10 hr⁻¹. The preferred WHSV is determined depending on the temperature. For example, at 300°C, WHSV is 0.02 to 2 hr⁻¹, and at 350°C, it is 0.1 to 5 hr⁻¹.

[0034] In the reaction of the amine compound as a starting material, it may be diluted with an inert gas such as hydrogen, nitrogen, steam or hydrocarbons, or with an inert solvent such as water and inert hydrocarbons. By using these diluents, the reaction can be controlled appropriately.

EXAMPLE 1

Preparation of HZSM-5

[0035] A 40 g NaZSM-5 sample (obtained from Degussa AG Modul 180) was exchanged with 800 mL of 1.0 M aqueous NH₄NO₃ solution. The solid was filtered, washed with deionized water, and dried at 110°C to yield NH₄-ZSM-5. HZSM-5 was obtained by calcination of the NH₄-ZSM-5 at 500°C. Chemical analysis showed that the HZSM-5 had a silica/alumina molar ratio of 180 and contained less than 0.01 wt% Na.

EXAMPLE 2

Preparation of Base-treated HZSM-5

[0036] A 10 g NaZSM-5 sample (obtained from Degussa AG, Modul 180) was stirred in 250 mL of 2.0 M NaOH solution at room temperature for two hours. The solid was filtered, washed with deionized water and dried at 110°C. The base-treated sample was then exchanged with 200 mL of 1.0 M aqueous NH₄NO₃ solution to obtain NH₄-ZSM-5. HZSM-5 was obtained by calcination of the NH₄-ZSM-5 at 500°C. Chemical analysis showed that the HZSM-5 had a silica/alumina molar ratio of 153 and contained less than 0.01 wt% Na.

[0037] The catalysts of Examples 1 and 2 were characterized by infrared spectroscopy. Excess hydroxyl groups (broad band centered at 3458 cm⁻¹ in the spectrum) were present in the non-treated HZSM-5 material. These excess hydroxyl groups were successfully removed after base treatment as was evidenced by infrared spectroscopy.

EXAMPLES 3 AND 4

TEDA Synthesis

[0038] Reactions were carried out in a plug-flow reactor at atmospheric pressure. Typically, 1 cc (about 0.6 g) of catalyst particles of 18-35 mesh were loaded into the reactor. The reactor was heated to 340°C under a flow of nitrogen. Aqueous ethylenediamine (EDA) solution (25 wt%) was fed to the reactor with a syringe pump at 0.6 mL/hr. Nitrogen gas was co-fed to the reactor at 8 mL/min. Example 3 used the unmodified HZSM-5 catalyst from Example 1 while Example 4 used the HZSM-5 catalyst treated with sodium hydroxide from Example 2. The results in Table 1 show that base treatment not only increased the TEDA yield on the HZSM-5 catalyst, but also prevented catalyst deactivation as was observed for nontreated HZSM-5.

Table 1

	Catalyst NaOH Treatment	Time on Stream (hr)	EDA Conversion (%)	TEDA Molar Selectivity (%)
Example 3	No	6	88.0	21.0
		21	88.7	22.9
Example 4	Yes	6	100	58.3

Table 1 (continued)

	Catalyst NaOH Treatment	Time on Stream (hr)	EDA Conversion (%)	TEDA Molar Selectivity (%)
5		32	100	54.5

Catalyst load	0.8 g
Feed composition	EDA/H ₂ O (25/75 wt%)
Conditions	340°C, 1 atm, N ₂ = 8 cc/min

INDUSTRIAL APPLICATION

[0039] The present invention provides an improvement in the production of TEDA from amine compounds using a zeolite catalyst.

Claims

1. A process for preparing triethylenediamine by passing an amine compound having, in the molecule, a moiety represented by the following general formula

where x is oxygen or nitrogen, over a pentasil-type zeolite with a silica/metal oxide molar ratio of 12 : 1 or more at a temperature in the range of 100 to 450 °C, characterised in that said process comprises employing a pentasil-type zeolite in the hydrogen or ammonium form which has been treated with an aqueous caustic solution prior to its conversion to H⁺ or NH₄⁺ form.

2. The process of claim 1 in which the caustic is sodium or potassium hydroxide.
3. The process of claim 2 which uses a 0.1 to 5 molar aqueous caustic solution.
4. The process of claim 3 which uses 10 to 30 ml aqueous caustic solution/g zeolite.
5. The process of claim 3 in which the zeolite has a silica/metal oxide molar ratio of 25 : 1 to 1000 : 1.
6. The process of claim 5 in which the zeolite is a ZSM-5, ZSM-8 or ZSM-11 zeolite.
7. A process according to claim 1, in which the zeolite is a ZSM-5 zeolite in the hydrogen or ammonium form and the aqueous caustic solution is a 0.1 to 5 molar aqueous sodium or potassium solution.
8. The process of claim 7, in which the amine compound is selected from ethanolamine, an ethyleneamine, a piperazine or morpholine.
9. The process of claim 7 in which the amine compound is ethylenediamine.
10. The process of claim 3 which uses 10 to 30 ml aqueous caustic solution/g zeolite.
11. The process of claim 7 in which the zeolite has a silica/alumina molar ratio of 25 : 1 to 1000 : 1.
12. A process according to claim 1 in which the amine compound is selected from an ethanolamine, an ethyleneamine, a piperazine or morpholine, the zeolite is a ZSM-5 zeolite in the hydrogen or ammonium form having a silica/alumina molar ratio of 25 : 1 to 1000 : 1 and the aqueous caustic solution is a 0.1 to 5 molar aqueous caustic solution.
13. The process of claim 12 in which the zeolite has a silica/alumina molar ratio of 50 : 1 to 500 : 1.

EP 0 831 096 B1

Patentansprüche

1. Verfahren zur Herstellung von Triethylendiamin durch Leiten einer Aminverbindung, die im Molekül eine Komponente der folgenden allgemeinen Formel umfasst

in der x Sauerstoff oder Stickstoff ist, über einen Zeolithen vom Pentasiltyp mit einem Molverhältnis von Siliciumdioxid zu Metalloxid von 12 : 1 oder mehr bei einer Temperatur im Bereich von 100 bis 450°C, dadurch gekennzeichnet, dass das Verfahren den Einsatz eines Zeolithen vom Pentasiltyp in der Wasserstoff- oder Ammoniumform umfasst, der vor seiner Umwandlung zur H⁺- oder NH₄⁺-Form mit einer wässrigen Ätzlösung behandelt wurde.

2. Verfahren nach Anspruch 1, bei dem die Ätzlösung Natrium- oder Kaliumhydroxid ist.
3. Verfahren nach Anspruch 2, das eine 0,1 bis 5-molare wässrige Ätzlösung verwendet.
4. Verfahren nach Anspruch 3, das 10 bis 30 ml wässrige Ätzlösung pro Gramm Zeolith verwendet.
5. Verfahren nach Anspruch 3, bei dem der Zeolith ein Molverhältnis von Siliciumdioxid zu Metalloxid von 25 : 1 bis 1000 : 1 hat.
6. Verfahren nach Anspruch 5, bei dem der Zeolith ein ZSM-5, ZSM-8 oder ZSM-11 Zeolith ist.
7. Verfahren nach Anspruch 1, bei dem der Zeolith ein ZSM-5 Zeolith in der Wasserstoff- oder Ammoniumform und die wässrige Ätzlösung eine 0,1 bis 5-molare wässrige Natrium- oder Kaliumlösung ist.
8. Verfahren nach Anspruch 7, bei dem die Aminverbindung aus Ethanolamin, einem Ethylenamin, einem Piperazin oder Morpholin ausgewählt ist.
9. Verfahren nach Anspruch 7, bei dem die Aminverbindung Ethylendiamin ist.
10. Verfahren nach Anspruch 3, bei dem 10 bis 30 ml wässrige Ätzlösung pro Gramm Zeolith verwendet werden.
11. Verfahren nach Anspruch 7, bei dem der Zeolith ein Molverhältnis von Siliciumdioxid zu Aluminiumoxid von 25 : 1 bis 1000 : 1 hat.
12. Verfahren nach Anspruch 1, bei dem die Aminverbindung aus einem Ethanolamin, einem Ethylenamin, einem Piperazin oder Morpholin ausgewählt ist, der Zeolith ein ZSM-5-Zeolith in der Wasserstoff- oder Ammoniumform mit einem Molverhältnis von Siliciumdioxid zu Aluminiumoxid von 25 : 1 bis 1000 : 1 ist und die wässrige Ätzlösung eine 0,1- bis 5-molare wässrige Ätzlösung ist.
13. Verfahren nach Anspruch 12, bei dem der Zeolith ein Molverhältnis von Siliciumdioxid zu Aluminiumoxid von 50 : 1 bis 500 : 1 hat.

Revendications

1. Procédé de préparation de triéthylènediamine selon on fait passer une amine ayant dans la molécule un fragment représenté par la formule générale suivante

dans laquelle x est un atome d'oxygène ou d'azote, sur une zéolite de type pentasil ayant un rapport molaire silice/oxyde métallique d'au moins 12:1, à une température comprise entre 100 et 450°C, caractérisé en ce que ledit procédé comprend l'utilisation d'une zéolite de type pentasil sous la forme hydrogène ou ammonium qui a été traitée avec une solution aqueuse d'une base caustique avant sa conversion en forme H⁺ ou NH₄⁺.

EP 0 831 096 B1

2. Procédé selon la revendication 1, dans lequel la base caustique est l'hydroxyde de sodium ou de potassium.
3. Procédé selon la revendication 2, qui utilise une solution aqueuse d'une base caustique 0,1 à 5 M.
- 6 4. Procédé selon la revendication 3, qui utilise 10 à 30 ml de solution aqueuse de base caustique par g de zéolite.
5. Procédé selon la revendication 3, dans lequel la zéolite a un rapport molaire silice/oxyde métallique de 25:1 à 1 000:1.
- 10 6. Procédé selon la revendication 5, dans lequel la zéolite est une zéolite ZSM-5, ZSM-8 ou ZSM-11.
7. Procédé selon la revendication 1, dans lequel la zéolite est une zéolite ZSM-5 sous la forme hydrogène ou ammonium, et la solution aqueuse de base caustique est une solution aqueuse de sodium ou de potassium 0,1 à 5 M.
- 15 8. Procédé selon la revendication 7, dans laquelle l'amine est choisie parmi une éthanolamine, une éthylène-amine, une pipérazine ou une morpholine.
9. Procédé selon la revendication 7, dans lequel l'amine est l'éthylènediamine.
- 20 10. Procédé selon la revendication 3, qui utilise 10 à 30 ml de solution aqueuse de base caustique par g de zéolite.
11. Procédé selon la revendication 7, dans lequel la zéolite a un rapport molaire silice/alumine de 25:1 à 1 000:1.
- 25 12. Procédé selon la revendication 1, dans lequel l'amine est choisie parmi une éthanolamine, une éthylène-amine, une pipérazine ou une morpholine, la zéolite est une zéolite ZSM-5 sous la forme hydrogène ou ammonium ayant un rapport molaire silice/alumine de 25:1 à 1 000:1 et la solution aqueuse de base caustique est une solution aqueuse de base caustique 0,1 à 5 M.
- 30 13. Procédé selon la revendication 12, dans lequel la zéolite a un rapport molaire silice/alumine de 50:1 à 500:1.
